34

35 **To date severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) has infected**
36 **nearly 100 million individuals resulting in over two million deaths. Many vaccines are**
37 **being deployed to prevent coronavirus disease-2019 (COVID-19) including two novel**
38 **mRNA-based vaccines^{1,2}. These vaccines elicit neutralizing antibodies and appear to be safe**
39 **and effective, but the precise nature of the elicited antibodies is not known³⁻⁵. Here we**
40 **report on the antibody and memory B cell responses in a cohort of 20 volunteers who**
41 **received either the Moderna (mRNA-1273) or Pfizer-BioNTech (BNT162b2) vaccines.**
42 **Consistent with prior reports, 8 weeks after the second vaccine injection volunteers showed**
43 **high levels of IgM, and IgG anti-SARS-CoV-2 spike protein (S), receptor binding domain**
44 **(RBD) binding titers^{3,5}. Moreover, the plasma neutralizing activity, and the relative**
45 **numbers of RBD-specific memory B cells were equivalent to individuals who recovered**
46 **from natural infection^{6,7}. However, activity against SARS-CoV-2 variants encoding E484K**
47 **or N501Y or the K417N:E484K:N501Y combination was reduced by a small but significant**
48 **margin. Consistent with these findings, vaccine-elicited monoclonal antibodies (mAbs)**
49 **potently neutralize SARS-CoV-2, targeting a number of different RBD epitopes epitopes in**
50 **common with mAbs isolated from infected donors. Structural analyses of mAbs complexed**
51 **with S trimer suggest that vaccine- and virus-encoded S adopts similar conformations to**
52 **induce equivalent anti-RBD antibodies. However, neutralization by 14 of the 17 most**
53 **potent mAbs tested was reduced or abolished by either K417N, or E484K, or N501Y**
54 **mutations. Notably, the same mutations were selected when recombinant vesicular**
55 **stomatitis virus (rVSV)/SARS-CoV-2 S was cultured in the presence of the vaccine elicited**
56 **mAbs. Taken together the results suggest that the monoclonal antibodies in clinical use**

- 57 **should be tested against newly arising variants, and that mRNA vaccines may need to be**
- 58 **updated periodically to avoid potential loss of clinical efficacy.**

59 Between 19 October 2020 and 15 January 2021, 20 volunteers who received two doses of the
60 Moderna (n=14) or Pfizer-BioNTech mRNA (n=6) vaccines were recruited for blood donation
61 and analyzed. Ages of the analyzed volunteers ranged from 29-69 years (median 43); 12
62 (60%) were male and 8 (40%) female. 16 participants identified as Caucasian, 2 as Hispanic, and
63 1 as African American or Asian, respectively. The time from the second vaccination to sample
64 collection varied between 3-14 weeks with an average of 8 weeks. None of the volunteers had a
65 history of prior SARS-CoV-2 infection and none experienced serious adverse events after
66 vaccination (Extended Data Table 1).

67

68 **Vaccinee plasma binding and neutralizing activity against SARS-CoV-2**

69 Plasma IgM and IgG anti-SARS-CoV-2 S and RBD were measured by enzyme-linked
70 immunosorbent assay (ELISA)^{6,7}. All individuals tested showed reactivity to S and RBD that
71 was significantly higher compared to pre-COVID-19 historic controls (Extended Data Fig 1). As
72 might be expected anti-S and -RBD IgG levels were higher than IgM or IgA. Moreover, there
73 was greater variability in the anti-RBD than the anti-S response but the two were positively
74 correlated (Extended Data Fig 1).

75

76 Plasma neutralizing activity was determined using HIV-1 pseudotyped with SARS-CoV-2 S
77 protein⁶⁻⁸. In agreement with previous reports, there was a broad range of plasma neutralizing
78 activity 3-14 weeks after the second vaccine dose that was similar to that elicited by natural
79 infection in a convalescent cohort after 1.3 months, and greater than the activity at 6.2 months
80 after infection (Fig. 1a, Extended Data Table 1). There was no significant difference in
81 neutralizing activity between the Moderna and Pfizer-BioNTech vaccines (Fig. 1b). As

82 expected, plasma neutralizing activity was directly correlated to anti-S and -RBD binding titers
83 in ELISAs^{6,7} (Fig. 1c, d, and Extended Data Fig. 2a-d) . Finally, RBD and S binding, and
84 neutralizing activities were directly correlated to the time between the first vaccine dose and
85 blood donation with significantly reduced levels in all 3 measurements with time (Fig. 1e-g, and
86 Extended Data Fig. 2e-h)⁹.

87

88 To determine whether plasma from vaccinated individuals can neutralize circulating SARS-CoV-
89 2 variants of concern and mutants that arise *in vitro* under antibody pressure^{10,11}, we tested
90 vaccinee plasma against a panel of 10 mutant pseudotype viruses including recently reported
91 N501Y (B.1.1.7 variant), K417N, E484K and the combination of these 3 RBD mutations
92 (501Y.V2 variant)¹²⁻¹⁷. Vaccinee plasma was significantly less effective in neutralizing the HIV-
93 1 virus pseudotyped with certain SARS-CoV-2 mutant S proteins (Fig. 1h and i and Extended
94 Data Fig. 2j). Among the volunteer plasmas tested there was an 1 to 3, 1.3 to 2.5, and 1.1 to 3
95 fold decrease in neutralizing activity against E484K, N501Y and the K417N:E484K:N501Y
96 combination respectively (p= 0.0033, p=0.0002, and p<0.0001, respectively, Fig. 1h and i). We
97 conclude that the plasma neutralizing activity elicited by mRNA vaccination is variably but
98 significantly less effective against particular RBD mutants in the tested panel.

99

100 **Vaccine-elicited SARS-CoV-2 RBD-specific monoclonal antibodies**

101 Although circulating antibodies derived from plasma cells wane over time, long-lived immune
102 memory can persist in expanded clones of memory B cells⁶. We used flow cytometry to
103 enumerate the circulating SARS-CoV-2 RBD-specific memory B cells elicited by mRNA
104 immunization^{6,7} (Fig. 2a, Extended Data Fig. 3a and b). Notably, the percentage of RBD-binding

105 memory B cells in vaccinees was significantly greater than in naturally infected individuals
106 assayed after 1.3 months, but similar to the same individuals assayed after 6.2 months (Fig. 2b).
107 The percentage of RBD-binding memory B cells in vaccinees was not correlated to the time after
108 vaccination (Extended Data Fig. 3c). Thus, mRNA vaccination elicits a robust SARS-CoV-2
109 RBD-specific B cell memory response that resembles natural infection.

110
111 To examine the nature of the antibodies produced by memory B cells in response to vaccination,
112 we obtained 1,409 paired antibody heavy and light chains from RBD binding single B cells from
113 14 individuals (n=10 Moderna and n=4 Pfizer-BioNTech vaccinees) (Extended Data Table 2).
114 Expanded clones of cells comprised 4-50% of the overall RBD binding memory B cell
115 compartment (Fig. 2c and d, and Extended Data Fig. 3d). Similar to natural infection, IGVH 3-
116 53, and 3-30 and some IGVL genes were significantly over-represented in the RBD-binding
117 memory B cell compartment of vaccinated individuals (Fig. 2e, Extended Data Fig. 4a). In
118 addition, antibodies that share the same combination of IGHV and IGLV genes in vaccinees
119 comprised 39% of all the clonal sequences (Extended Data Fig. 4b) and 59% when combined
120 with naturally infected individuals^{6,7} (Fig. 2f), and some of these antibodies were nearly identical
121 (Extended Data Table 2 and 3). The number of V gene nucleotide mutations in vaccinees is
122 greater than in naturally infected individuals assayed after 1.3 months, but lower than that in the
123 same individuals assayed after 6.2 months (Fig. 2g and Extended Data Fig. 5a). The length of the
124 IgH CDR3 was similar in both natural infected individuals and vaccinees and hydrophobicity
125 was below average¹⁸ (Fig. 2h and Extended Data Fig. 5a and b). Thus, the IgG memory response
126 is similar in individuals receiving the Pfizer-BioNTech and Moderna vaccines and both are rich
127 in recurrent and clonally expanded antibody sequences.

128
129 Eighty-four representative antibodies from 4 individuals were expressed and tested for reactivity
130 to the RBD (Extended Data Table 4). The antibodies included: (1) 58 that were randomly
131 selected from those that appeared only once, and (2) 26 representatives of expanded clones. Of
132 the antibodies tested 99% (83 out of the 84) bound to RBD indicating that single cell sorting by
133 flow cytometry efficiently identified B cells producing anti-RBD antibodies (Extended Data Fig.
134 6a and b and Table 4). In anti-RBD ELISAs the mean half-maximal effective concentration
135 (EC_{50}) was higher than that observed in infected individuals after 6 months but not significantly
136 different from antibodies obtained 1.3 months after infection (Extended Data Fig. 6a, and Table
137 4 and ^{6,7}). To examine memory B cell antibodies for binding to circulating SARS-CoV-2 variants
138 and antibody resistant mutants we performed ELISA assays using mutant RBDs^{10,13,19-22}.
139 Twenty-two (26%) of the antibodies showed at least 5-fold decreased binding to at least one of
140 the mutant RBDs (Extended data Fig. 6c-l, and Table 4).

141
142 SARS-CoV-2 S pseudotyped viruses were used to measure the neutralizing activity of all 84
143 antibodies⁶⁻⁸ (Fig. 3a, Extended Data Table 4). Consistent with the plasma neutralization results,
144 the geometric mean neutralization half-maximal inhibitory concentration of the vaccinee
145 antibodies (IC_{50} =151 ng/ml) was not significantly different to antibody collections obtained from
146 naturally infected individuals 1.3 or 6.2 months after infection (Fig. 3a and ^{6,7}).

147
148 To examine the neutralizing breadth of the monoclonal antibodies and begin to map their target
149 epitopes we tested the 17 most potent antibodies (Extended data Table 5), 8 of which carried
150 IgHV3-53, against a panel of 12 SARS-CoV-2 variants: A475V is resistant to class 1 antibodies

151 (structurally defined as described²⁰); E484K and Q493R are resistant to class 2
152 antibodies^{6,7,10,11,20,21,23,24}; while R346S, N439K, and N440K are resistant to class 3
153 antibodies^{6,7,10,11,20,24}. Additionally, K417N, Y453F, S477R, N501Y, D614G, and R683G
154 represent circulating variants some of which have been associated with rapidly increasing case
155 numbers^{12,13,24-27}. Based on their neutralizing activity against the variants, all but 3 of the
156 antibodies were provisionally assigned to a defined antibody class or a combination (Fig. 3b). As
157 seen in natural infection, a majority of the antibodies tested (9/17) were at least ten-fold less
158 effective against pseudotyped viruses carrying the E484K mutation^{6,10,20}. In addition, 5 of the
159 antibodies were less potent against K417N and 4 against N501Y by ten-fold or more (Fig. 3b).
160

161 To determine whether antibody-imposed selection pressure could also drive the emergence of
162 resistance mutations *in vitro*, we cultured an rVSV/SARS-CoV-2 recombinant virus in the
163 presence of each of 18 neutralizing monoclonal antibodies. All of the tested antibodies selected
164 for RBD mutations. Moreover, in all cases the selected mutations corresponded to residues in the
165 binding sites of their presumptive antibody class (Fig. 3b and c). For example, antibody 627,
166 which was assigned to class 2 based on sensitivity to E484K mutation, selected for the
167 emergence of the E484K mutation *in vitro* (Fig 3c). Notably, 6 of the antibodies selected for
168 K417N E or T, 5 selected for E484K and 3 selected for N501Y, T or H, which coincide with
169 mutations present in the circulating B1.1.17, 501Y.V2 and B1.1.28/501.V3 variants that have
170 been associated with rapidly increasing case numbers in particular locales^{12,15,17,28}.

171

172 **Cryo-EM mapping of antibody epitopes**

173 To further characterize antibody epitopes and mechanisms of neutralization, we characterized
174 seven complexes between mAb Fab fragments and the prefusion, stabilized ectodomain trimer of
175 SARS-CoV-2 S glycoprotein²⁹ using single-particle cryo-EM (Fig. 4 and Extended Data Table
176 6). Overall resolutions ranged from 5-8 Å and coordinates from S trimer and representative Fab
177 crystal structures were fit by rigid body docking into the cryo-EM density maps to provide a
178 general assessment of antibody footprints/RBD epitopes. Fab-S complexes exhibited multiple
179 RBD-binding orientations recognizing either ‘up’/‘down’ (Fig. 4a-j) or solely ‘up’ (Fig. 4k-n)
180 RBD conformations, consistent with structurally defined antibody classes from natural infection
181 (Fig. 4o)²⁰. The majority of mAbs characterized (6 of 7) recognized epitopes that included RBD
182 residues involved in ACE2 recognition, suggesting a neutralization mechanism that directly
183 blocks ACE2-RBD interactions. Additionally, structurally defined antibody epitopes were
184 consistent with RBD positions that were selected in rVSV/SARS-CoV-2 recombinant virus
185 outgrowth experiments, including residues K417, N439/N440, E484, and N501 (Fig. 3c and Fig.
186 4f-j,m,n). Taken together, these data suggest that functionally similar antibodies are raised during
187 vaccination and natural infection, and that the RBDs of spike trimers translated from the mRNA
188 delivered by vaccination adopt a similar distribution of ‘up’/‘down’ conformations as observed
189 on SARS-CoV-2 virions.

190

191 **Discussion**

192 The mRNA-based SARS-CoV-2 vaccines are safe and effective and being deployed globally to
193 prevent infection and disease. The vaccines elicit antibody responses against the RBD, the major
194 target of neutralizing antibodies³⁰⁻³⁵, in a manner that resembles natural infection. Notably, the
195 neutralizing antibodies produced by mRNA vaccination target the same epitopes as natural

196 infection. The data is consistent with SARS-CoV-2 spike trimers translated from the injected
197 RNA adopting the range of conformations available to spikes on the surfaces of virions.
198 Moreover, different individuals immunized with either the Moderna (mRNA-1273) or Pfizer-
199 BioNTech (BNT162b2) vaccines produce closely related and nearly identical antibodies.

200

201 Human neutralizing monoclonal antibodies to the SARS-CoV-2 RBD can be categorized as
202 belonging to 4 different classes based on their target regions on the RBD²⁰. Class 1 and 2
203 antibodies are among the most potent and also the most abundant antibodies^{6,7,30,31,34}. These
204 antibodies target epitopes that overlap or are closely associated with RBD residues K417, E484
205 and N501. They are frequently sensitive to mutation in these residues and select for K417N,
206 E484K and N501Y mutations in both yeast and VSV expressing SARS-CoV-2 S proteins^{10,13,24}.
207 To avert selection and escape, antibody therapies should be composed of combinations of
208 antibodies that target non-overlapping epitopes^{7,10,11,24,36-38}.

209

210 A number of circulating SARS-CoV-2 variants that have been associated with rapidly increasing
211 case numbers and have particular prevalence in the UK (B.1.1.7/501Y.V1), South Africa
212 (501Y.V2) and Brazil (B.1.1.28/501.V3)^{12,15,17,28,39}. Our experiments indicate that these variants,
213 and potentially others that carry K417N/T, E484K and N501Y mutations, can reduce the
214 neutralization potency of vaccinee plasma. The comparatively modest effects of the mutations on
215 viral sensitivity to plasma reflects the polyclonal nature of the neutralizing antibodies in vaccinee
216 plasma. Nevertheless, emergence of these particular variants is consistent with the dominance of
217 the class 1 and 2 antibody response in infected or vaccinated individuals and raises the
218 possibility that they emerged in response to immune selection in individuals with non-sterilizing

219 immunity. What the long-term effect of accumulation of mutations on the SARS-CoV-2
220 pandemic will be is not known, but the common cold coronavirus HCoV-229E evolves antigenic
221 variants that are comparatively resistant to the older sera but remain sensitive to
222 contemporaneous sera⁴⁰. Thus, it is possible that these mutations and others that emerge in
223 individuals with suboptimal or waning immunity will erode the effectiveness of natural and
224 vaccine elicited immunity. The data suggests that SARS-CoV-2 vaccines may need to be updated
225 and immunity monitored in order to compensate for viral evolution.

226

227 **Figure Legends**

228

229 **Fig. 1. Plasma neutralizing activity.** **a**, SARS-CoV-2 pseudovirus neutralization assay. NT₅₀

230 values for COVID-19 convalescent plasma measured at 1.3 months⁷ and 6.2 months⁶ as well as

231 plasma from mRNA-vaccinees. NT₅₀ values lower than 10 were plotted at 10. Mean of 2

232 independent experiments. Red bars and indicated values represent geometric mean NT₅₀ values.

233 Statistical significance was determined using the two-tailed Mann-Whitney U-test. **b**, NT₅₀

234 values for Moderna (black) and Pfizer-BioNTech (red) vaccine recipients. Red bars and

235 indicated values represent geometric mean NT₅₀ values. Statistical significance was determined

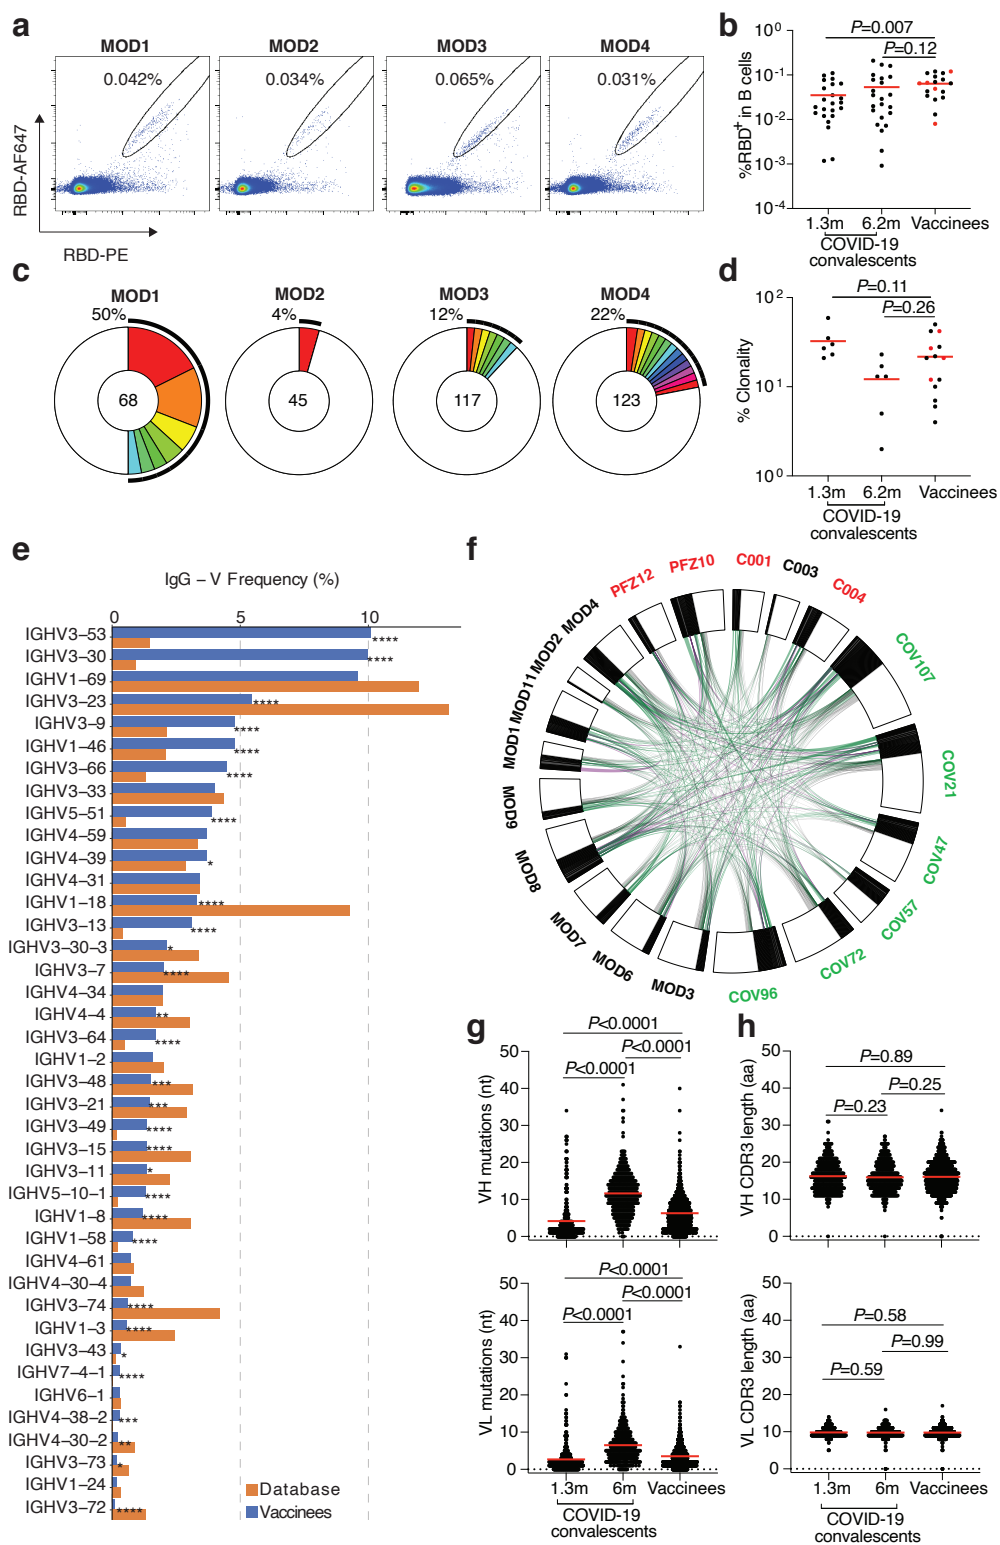

236 using the two-tailed Mann-Whitney U-test. **c**, Anti-RBD IgG AUC (Y axis) plotted against NT₅₀

237 (X axis) $r=0.84$, $p<0.0001$. **d**, Anti-S IgG AUC (Y axis) plotted against NT₅₀ (X axis) $r=0.83$,

238 $p<0.0001$. **e**, Anti-RBD IgG AUC (Y axis) plotted against time between first dose

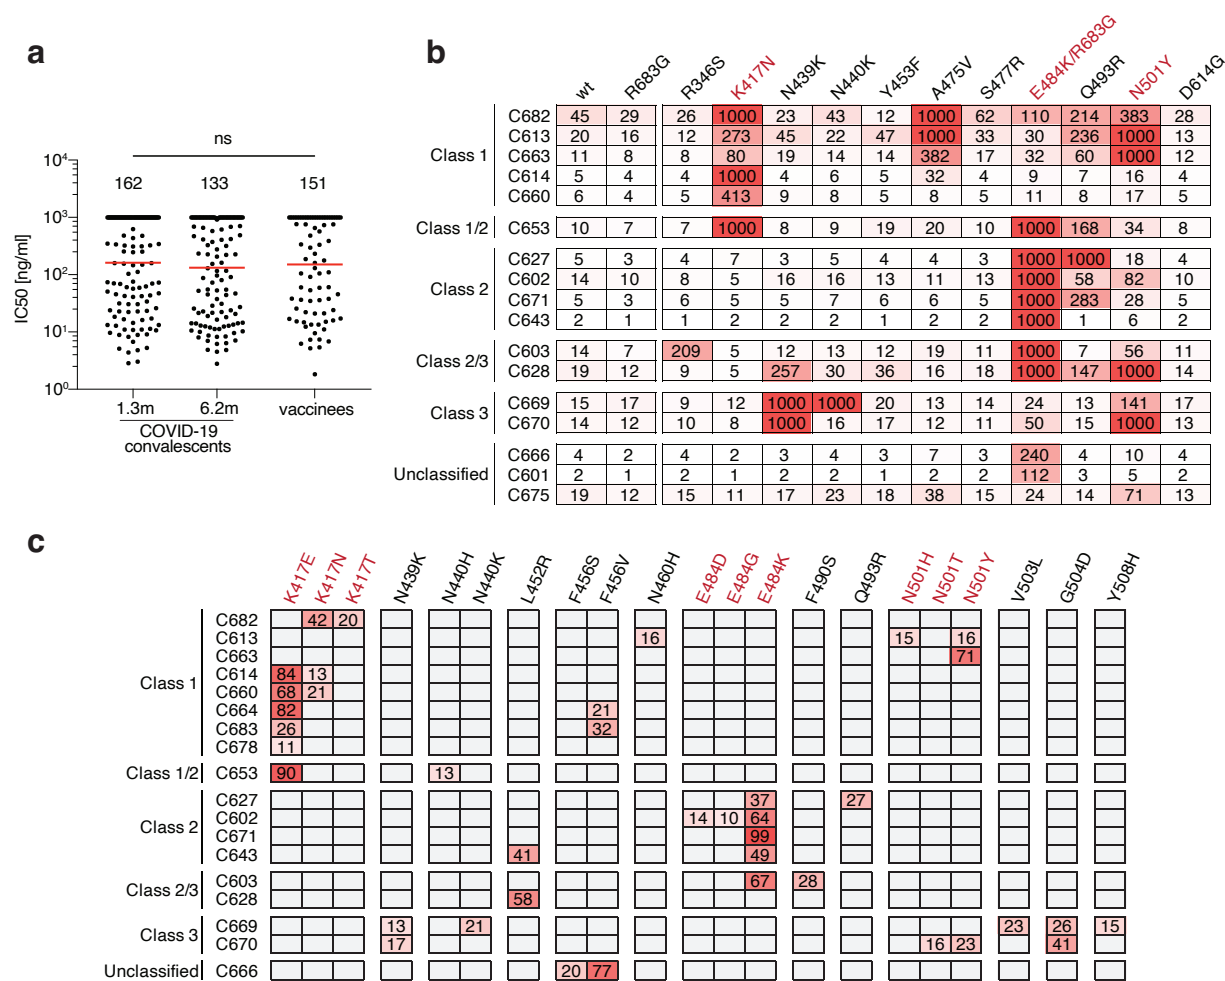

239 draw (X axis) $r=-0.60$ $p=0.0055$. **f**, Anti-S IgG AUC (Y axis) plotted against time between first

240 dose and blood draw (X axis) $r=-0.62$ $p=0.0038$. **g**, NT₅₀ (Y axis) plotted against time between
241 first dose and blood draw (X axis) $r=-0.69$ $p=0.0008$. The r and p values for correlations in **c-g**
242 were determined by two-tailed Spearman correlation. Moderna vaccinees are in black and Pfizer-
243 BioNTech in red. **h**. Examples of neutralization assays, comparing the sensitivity of pseudotyped
244 viruses with WT and RBD mutant SARS-CoV-2 S proteins to vaccinee plasma. **i**, NT50 values
245 for vaccinee plasma (n=15) neutralization of pseudotyped viruses with WT and the indicated
246 RBD-mutant SARS-CoV-2 S proteins. Statistical significance was determined using one tailed t-
247 test. All experiments were performed a minimum of 2 times. Pfizer-BioNTech vaccinees in red.
248

250 **Fig. 2. Memory B cell antibodies. a**, Representative flow cytometry plots showing dual
251 AlexaFluor-647-RBD and PE-RBD binding B cells for 4 vaccinees. **b**, as in **a**, dot plot
252 summarizes the percentage of RBD binding B cells in 19 vaccinees, in comparison to a cohort of
253 infected individuals assayed 1.3 and 6.2 months after infection^{6,7}. Individuals who received the
254 Moderna vaccine are shown in black and Pfizer-BioNTech vaccine recipients in red. Red
255 horizontal bars indicate mean values. Statistical significance was determined using two-tailed
256 Mann–Whitney U-tests. **c**, Pie charts show the distribution of antibody sequences from the 4
257 individuals in **a**. The number in the inner circle indicates the number of sequences analyzed. Pie
258 slice size is proportional to the number of clonally related sequences. The black outline indicates
259 the frequency of clonally expanded sequences. **d**, as in **c**, graph shows relative clonality among
260 14 vaccinees assayed, individuals who received the Moderna vaccine are shown in black and
261 Pfizer-BioNTech vaccine recipients in red. Red horizontal bars indicate mean values. Statistical
262 significance was determined using two-tailed Mann–Whitney U-tests. **e**, Graph shows relative
263 abundance of human IGVH genes Sequence Read Archive accession SRP010970 (orange), and
264 vaccinees (blue). A two-sided binomial test was used to compare the frequency distributions,
265 significant differences are denoted with stars (* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** = $p <$
266 0.0001). **f**, Clonal relationships between sequences from 14 vaccinated individuals (Moderna in
267 black, Pfizer-BioNTech in red Extended Data Table 2) and naturally infected individuals (in
268 green, from^{6,7}). Interconnecting lines indicate the relationship between antibodies that share V
269 and J gene segment sequences at both IGH and IGL. Purple, green and grey lines connect related
270 clones, clones and singles, and singles to each other, respectively. **g**, Number of somatic
271 nucleotide mutations in the IGVH (top) and IGVL (bottom) in vaccinee antibodies (Extended
272 Data Table 2) compared to natural infection obtained 1.3 or 6.2 months after infection^{6,7}.

273 Statistical significance was determined using the two-tailed Mann–Whitney U-tests and red
274 horizontal bars indicate mean values. **h**, as in **g**, but for CDR3 length.
275

276
 277 **Fig. 3: Anti-SARS-CoV-2 RBD monoclonal antibody neutralizing activity. a,** SARS-CoV-2
 278 pseudovirus neutralization assay. IC₅₀ values for antibodies cloned from COVID-19
 279 convalescent patients measured at 1.3 and 6.2 months^{6,7} as well as antibodies cloned from
 280 mRNA-vaccinees. Antibodies with IC₅₀ values above 1000 ng/ml were plotted at 1000 ng/ml.
 281 Mean of 2 independent experiments. Red bars and indicated values represent geometric mean
 282 IC₅₀ values in ng/ml. Statistical significance was determined using the two-tailed Mann-Whitney
 283 U-test. **b,** IC₅₀ values for 17 selected mAbs for neutralization of wild type and the indicated
 284 mutant SARS-CoV-2 pseudoviruses. Color gradient indicates IC₅₀ values ranging from 0 (white)

285 to 1000 ng/ml (red). **c**, Antibody selection pressure can drive emergence of S variants in cell
286 culture; the percentage of sequence reads encoding the indicated RBD mutations after a single
287 passage of rVSV/SARS-CoV-2 in the presence of the indicated antibodies is tabulated. Color
288 gradient indicates percentage of sequence reads bearing the indicated mutation ranging from 0
289 (white) to 100 (red). Positions for which no sequence read was detected are shown in grey.
290 K417N, E484K/R683G and N501 are highlighted in b and c as they constitute important
291 circulating variants.
292

293

294 **Fig. 4. Cryo-EM reconstructions of Fab-S complexes.** Cryo-EM densities for Fab-S

295 complexes (a-e; k-l) and close-up views of antibody footprints on RBDs (f-j; m-n) are shown for

296 neutralizing mAbs. As expected due to Fab inter-domain flexibility, cryo-EM densities (a-e; k-l)

297 were weak for the Fab C_H-C_L domains. Models of antibody footprints on RBDs (f-j; m-n) are

298 presented as Fab V_H-V_L domains (cartoon) complexed with the RBD (surface). To generate
299 models, coordinates of stabilized S trimer (PDB 6XKL) and representative Fab fragments (PDB
300 6XCA or 7K8P) with CDR3 loops removed were fit by rigid body docking into the cryo-EM
301 density maps. **a,f**, C669; **b,g**, C643; **c,h**, C603; **d,i**, C601; **e,j**, C670; **k,m**, C666; and **l,n**, C663.
302 RBD residues K417, N439, N440, E484, and N501 are highlighted as red surfaces. The N343
303 glycan is shown as a teal sphere. **o**, Composite model illustrating targeted epitopes of RBD-
304 specific neutralizing mAbs (shown as V_H-V_L domains in colors from panels **a-l**) elicited from
305 mRNA vaccines.
306

307 **Methods**

308 **Data reporting**

309 No statistical methods were used to predetermine sample size. The experiments were not
310 randomized and the investigators were not blinded to allocation during experiments and outcome
311 assessment.

312

313 **Study participants.**

314 To isolate and characterize anti-SARS-CoV-2 RBD antibodies from vaccinees, a cohort
315 of 20 individuals that participated in either the Moderna or Pfizer-BioNTech phase 3 vaccine
316 clinical trials and did not report prior history of SARS-CoV-2 infection was recruited at the NIH
317 Blood Center and the Rockefeller University Hospital for blood donation. Eligible participants
318 included adults, at least 18 years of age with no known heart, lung, kidney disease or bleeding
319 disorders, no history of HIV-1 or malaria infection. All participants were asymptomatic at the
320 time of the study visit and had received a complete 2 dose regimen of either mRNA vaccine.
321 Informed consent was obtained from all participants and the study was conducted in accordance
322 with Good Clinical Practice. The study visits and blood draws were reviewed and approved
323 under the National Institutes of Health's Federalwide Assurance (FWA00005897), in accordance
324 with Federal regulations 45 CFR 46 and 21 CFR 5 by the NIH Intramural Research Program IRB
325 committee (IRB# 99CC0168, Collection and Distribution of Blood Components from Healthy
326 Donors for In Vitro Research Use) and by the Institutional Review Board of the Rockefeller
327 University (IRB# DRO-1006, Peripheral Blood of Coronavirus Survivors to Identify Virus-
328 Neutralizing Antibodies). For detailed participant characteristics see Extended Data Table SI 1.
329

330 **Blood samples processing and storage.**

331 Samples collected at NIH were drawn from participants at the study visit and processed within
332 24 hours. Briefly, whole blood samples were subjected to Ficoll gradient centrifugation after 1:1
333 dilution in PBS. Plasma and PBMC samples were obtained through phase separation of plasma
334 layer and Buffy coat phase, respectively. PBMCs were further prepared through centrifugation,
335 red blood cells lysis and washing steps, and stored in CellBanker cell freezing media
336 (Amsbio). All samples were aliquoted and stored at - 80 °C and shipped on dry ice. Prior to
337 experiments, aliquots of plasma samples were heat-inactivated (56°C for 1 hour) and then stored
338 at 4°C. Peripheral Blood Mononuclear Cells (PBMCs) obtained from samples collected at
339 Rockefeller University were purified as previously reported^{6,7} by gradient centrifugation and
340 stored in liquid nitrogen in the presence of FCS and DMSO. Heparinized plasma samples were
341 aliquoted and stored at -20°C or less. Prior to experiments, aliquots of plasma samples were heat-
342 inactivated (56°C for 1 hour) and then stored at 4°C.

343

344

345 **ELISAs**

346 ELISAs^{41,42} to evaluate antibodies binding to SARS-CoV-2 S (BioHub), RBD and additional
347 mutated RBDs were performed by coating of high-binding 96-half-well plates (Corning 3690)
348 with 50 µl per well of a 1µg/ml protein solution in PBS overnight at 4 °C. Plates were washed 6
349 times with washing buffer (1× PBS with 0.05% Tween-20 (Sigma-Aldrich)) and incubated with
350 170 µl per well blocking buffer (1× PBS with 2% BSA and 0.05% Tween-20 (Sigma)) for 1 h at
351 room temperature. Immediately after blocking, monoclonal antibodies or plasma samples were
352 added in PBS and incubated for 1 h at room temperature. Plasma samples were assayed at a

353 1:66.6 (RU samples) or a 1:33.3 (NIH samples) starting dilution and 7 additional threefold serial
354 dilutions. Monoclonal antibodies were tested at 10 µg/ml starting concentration and 10 additional
355 fourfold serial dilutions. Plates were washed 6 times with washing buffer and then incubated
356 with anti-human IgG, IgM or IgA secondary antibody conjugated to horseradish peroxidase
357 (HRP) (Jackson Immuno Research 109-036-088 109-035-129 and Sigma A0295) in blocking
358 buffer at a 1:5,000 dilution (IgM and IgG) or 1:3,000 dilution (IgA). Plates were developed by
359 addition of the HRP substrate, TMB (ThermoFisher) for 10 min (plasma samples) or 4 minutes
360 (monoclonal antibodies), then the developing reaction was stopped by adding 50 µl 1 M H₂SO₄
361 and absorbance was measured at 450 nm with an ELISA microplate reader (FluoStar Omega,
362 BMG Labtech) with Omega and Omega MARS software for analysis. For plasma samples, a
363 positive control (plasma from participant COV72^{6,7}, diluted 66.6-fold and with seven additional
364 threefold serial dilutions in PBS) was added to every assay plate for validation. The average of
365 its signal was used for normalization of all of the other values on the same plate with Excel
366 software before calculating the area under the curve using Prism V8.4 (GraphPad). For
367 monoclonal antibodies, the EC₅₀ was determined using four-parameter nonlinear regression
368 (GraphPad Prism V8.4).

369

370 **Expression of RBD proteins**

371 Mammalian expression vectors encoding the RBDs of SARS-CoV-2 (GenBank MN985325.1; S
372 protein residues 319-539) and eight additional mutant RBD proteins (E484K, Q493R, R346S,
373 N493K, N440K, V367F, A475V, S477N and V483A) with an N-terminal human IL-2 or Mu
374 phosphatase signal peptide were previously described²¹.

375

376 **Cells and viruses**

377 293T/ACE2.c122 and HT1080/ACE2.c114 cells⁸ were cultured in Dulbecco's Modified Eagle
378 Medium (DMEM) supplemented with 10% fetal bovine serum (FBS) at 37°C and 5% CO₂. Cells
379 were periodically tested for contamination with mycoplasma or retroviruses.
380 rVSV/SARS-CoV-2/GFP chimeric virus stocks were generated by infecting 293T/ACE2.c122
381 cells. Supernatant was harvested 1 day post infection (dpi), cleared of cellular debris, and stored
382 at -80°C. A plaque purified variant designated rVSV/SARS-CoV-2/GFP_{2E1} that encodes
383 D215G/R683G substitutions was used in these studies⁸.

384

385 **Selection and analysis of antibody escape mutations**

386 For the selection of monoclonal antibody-resistant spike variants, a rVSV/SARS-CoV-2/GFP_{2E1}
387 (for details see⁸) population containing 10⁶ infectious units was incubated with of monoclonal
388 antibodies (10 µg/ml passage 10-40 µg/ml for 1 hr at 37 °C. Then, the virus-antibody mixtures
389 were incubated with 5× 10⁵ 293T/ACE2c1.22 cells in 6-well plates. At 1 day post infection media
390 was replaced with fresh media containing the equivalent concentrations of antibodies.
391 Supernatant was harvested 2 days after infection and 150 µl of the cleared supernatant was used
392 to infect cells for passage 2, while 150 µl was subjected to RNA extraction and sequencing.
393 For identification of putative antibody resistance mutations, RNA was extracted using
394 NucleoSpin 96 Virus Core Kit (Macherey-Nagel). The RNA was reversed transcribed using the
395 SuperScript VILO cDNA Synthesis Kit (Thermo Fisher Scientific). KOD Xtreme Hot Start DNA
396 Polymerase (Millipore Sigma) was used for amplification of cDNA using primers flanking the S-
397 encoding sequence. The PCR products were purified and sequenced as previously described^{6,10}.
398 Briefly, tagmentation reactions were performed using 1ul diluted cDNA, 0.25 µl Nextera TDE1

399 Tagment DNA enzyme (catalog no. 15027865), and 1.25 μ l TD Tagment DNA buffer (catalog
400 no. 15027866; Illumina). Next, the DNA was ligated to unique i5/i7 barcoded primer
401 combinations using the Illumina Nextera XT Index Kit v2 and KAPA HiFi HotStart ReadyMix
402 (2X; KAPA Biosystems) and purified using AmPure Beads XP (Agencourt), after which the
403 samples were pooled into one library and subjected to paired-end sequencing using Illumina
404 MiSeq Nano 300 V2 cycle kits (Illumina) at a concentration of 12pM.
405 For analysis of the sequencing data, the raw paired-end reads were pre-processed to remove trim
406 adapter sequences and to remove low-quality reads (Phred quality score < 20) using BBDuk.
407 Reads were mapped to the rVSV/SARS-CoV-2/GFP sequence using Geneious Prime (Version
408 2020.1.2). Mutations were annotated using Geneious Prime, with a P-value cutoff of 10^{-6} .

409

410 **SARS-CoV-2 pseudotyped reporter virus**

411 A panel of plasmids expressing RBD-mutant SAR-CoV-2 spike proteins in the context of
412 pSARS-CoV-2-S _{Δ 19} have been described previously¹⁰. Additional substitutions were introduced
413 using either PCR primer-mediated mutagenesis or with synthetic gene fragments (IDT) followed
414 by Gibson assembly. The mutants E484K and KEN (K417N+E484K+N501Y) were constructed
415 in the context of a pSARS-CoV-2-S _{Δ 19} variant with a mutation in the furin cleavage site
416 (R683G). The NT50s and IC50 of these pseudotypes were compared to a wildtype SARS-CoV-2
417 (NC_045512) spike sequence carrying R683G in the subsequent analyses, as appropriate.
418 Generation of SARS-CoV-2 pseudotyped HIV-1 particles was performed as previously
419 described⁷. Briefly, 293T cells were transfected with pNL4-3 Δ Env-nanoluc and pSARS-CoV-2-
420 S _{Δ 19} and pseudotyped virus stocks were harvested 48 hours after transfection, filtered and stored
421 at -80°C.

422

423 **SARS-CoV-2 pseudotype neutralization assays**

424 Plasma or monoclonal antibodies from vaccine recipients were four-fold or five-fold serially
425 diluted and then incubated with SARS-CoV-2 pseudotyped HIV-1 reporter virus for 1 h at 37 °C.
426 The antibody and pseudotype virus mixture was added to 293T_{Ace2} cells⁷ (for comparisons of
427 plasma from COVID-19-convalescents and vaccine recipients) or HT1080ACE2.c114 cells⁸ (for
428 analysis of spike mutants with vaccine recipient plasma or monoclonal antibodies). After 48 h
429 cells were washed with PBS and lysed with Luciferase Cell Culture Lysis 5× reagent (Promega)
430 and Nanoluc Luciferase activity in lysates was measured using the Nano-Glo Luciferase Assay
431 System (Promega) with the Glomax Navigator (Promega). The relative luminescence units were
432 normalized to those derived from cells infected with SARS-CoV-2 pseudotyped virus in the
433 absence of plasma or monoclonal antibodies. The half-maximal neutralization titers for plasma
434 (NT₅₀) or half-maximal and 90% inhibitory concentrations for monoclonal antibodies (IC₅₀ and
435 IC₉₀, respectively) were determined using four-parameter nonlinear regression (least squares
436 regression method without weighting; constraints: top=1, bottom=0) (GraphPad Prism).

437

438 **Biotinylation of viral protein for use in flow cytometry**

439 Purified and Avi-tagged SARS-CoV-2 RBD was biotinylated using the Biotin-Protein Ligase-
440 BIRA kit according to manufacturer's instructions (Avidity) as described before⁷. Ovalbumin
441 (Sigma, A5503-1G) was biotinylated using the EZ-Link Sulfo-NHS-LC-Biotinylation kit
442 according to the manufacturer's instructions (Thermo Scientific). Biotinylated ovalbumin was
443 conjugated to streptavidin-BV711 (BD biosciences, 563262) and RBD to streptavidin-PE (BD
444 Biosciences, 554061) and streptavidin-AF647 (Biolegend, 405237)⁷.

445

446 **Flow cytometry and single cell sorting**

447 Single-cell sorting by flow cytometry was performed as described previously⁷. Briefly,
448 peripheral blood mononuclear cells were enriched for B cells by negative selection using a pan-
449 B-cell isolation kit according to the manufacturer's instructions (Miltenyi Biotec, 130-101-638).
450 The enriched B cells were incubated in FACS buffer (1× PBS, 2% FCS, 1 mM EDTA) with the
451 following anti-human antibodies (all at 1:200 dilution): anti-CD20-PECy7 (BD Biosciences,
452 335793), anti-CD3-APC-eFluor 780 (Invitrogen, 47-0037-41), anti-CD8-APC-eFluor 780
453 (Invitrogen, 47-0086-42), anti-CD16-APC-eFluor 780 (Invitrogen, 47-0168-41), anti-CD14-
454 APC-eFluor 780 (Invitrogen, 47-0149-42), as well as Zombie NIR (BioLegend, 423105) and
455 fluorophore-labelled RBD and ovalbumin (Ova) for 30 min on ice. Single
456 CD3⁻CD8⁻CD14⁻CD16⁻CD20⁺Ova⁻RBD-PE⁺RBD-AF647⁺ B cells were sorted into
457 individual wells of 96-well plates containing 4 µl of lysis buffer (0.5× PBS, 10 mM DTT, 3,000
458 units/ml RNasin Ribonuclease Inhibitors (Promega, N2615) per well using a FACS Aria III and
459 FACSDiva software (Becton Dickinson) for acquisition and FlowJo for analysis. The sorted cells
460 were frozen on dry ice, and then stored at -80 °C or immediately used for subsequent RNA
461 reverse transcription.

462

463 **Antibody sequencing, cloning and expression**

464 Antibodies were identified and sequenced as described previously⁷. In brief, RNA from single
465 cells was reverse-transcribed (SuperScript III Reverse Transcriptase, Invitrogen, 18080-044) and
466 the cDNA stored at -20 °C or used for subsequent amplification of the variable IGH, IGL and
467 IGK genes by nested PCR and Sanger sequencing. Sequence analysis was performed using

468 MacVector. Amplicons from the first PCR reaction were used as templates for sequence- and
469 ligation-independent cloning into antibody expression vectors. Recombinant monoclonal
470 antibodies and Fabs were produced and purified as previously described⁷.

471

472 **Cryo-EM sample preparation**

473 Expression and purification of SARS-CoV-2 6P stabilized S trimers²⁹ was conducted as
474 previously described⁴³. Purified Fab and S 6P trimer were incubated at a 1.1:1 molar ratio per
475 protomer on ice for 30 minutes prior to deposition on a freshly glow-discharged 300 mesh,
476 1.2/1.3 Quantifoil copper grid. Immediately before 3 μ l of complex was applied to the grid,
477 fluorinated octyl-malotiside was added to the Fab-S complex to a final detergent concentration of
478 0.02% w/v, resulting in a final complex concentration of 3 mg/ml. Samples were vitrified in
479 100% liquid ethane using a Mark IV Vitrobot after blotting for 3 s with Whatman No. 1 filter
480 paper at 22°C and 100% humidity.

481

482 **Cryo-EM data collection and processing**

483 Data collection and processing followed a similar workflow to what has been previously
484 described in detail²⁰. Briefly, micrographs were collected on a Talos Arctica transmission
485 electron microscope (Thermo Fisher) operating at 200 kV for all Fab-S complexes. Data were
486 collected using SerialEM automated data collection software⁴⁴ and movies were recorded with a
487 K3 camera (Gatan). For all datasets, cryo-EM movies were patch motion corrected for beam-
488 induced motion including dose-weighting within cryoSPARC v2.15⁴⁵ after binning super
489 resolution movies. The non-dose-weighted images were used to estimate CTF parameters using
490 cryoSPARC implementation of the Patch CTF job. Particles were picked using Blob picker and

491 extracted 4x binned and 2D classified. Class averages corresponding to distinct views with
492 secondary structure features were chosen and ab initio models were generated. 3D classes that
493 showed features of a Fab-S complex were re-extracted, unbinned (0.869 Å/pixel) and
494 homogenously refined with C1 symmetry. Overall resolutions were reported based on gold
495 standard FSC calculations.

496

497 **Cryo-EM Structure Modeling and Refinement**

498 Coordinates for initial complexes were generated by docking individual chains from reference
499 structures into cryo-EM density using UCSF Chimera⁴⁶ (S trimer: PDB 6KXL, Fab: PDB 6XCA
500 or 7K8P after trimming CDR3 loops and converting to a polyalanine model). Models were then
501 refined into cryo-EM maps by rigid body and real space refinement in Phenix⁴⁷ If the resolution
502 allowed, partial CDR3 loops were built manually in Coot⁴⁸ and then refined using real-space
503 refinement in Phenix.

504

505 **Computational analyses of antibody sequences**

506 Antibody sequences were trimmed based on quality and annotated using Igblastn v.1.14. with
507 IMGT domain delineation system. Annotation was performed systematically using Change-O
508 toolkit v.0.4.540⁴⁹. Heavy and light chains derived from the same cell were paired, and
509 clonotypes were assigned based on their V and J genes using in-house R and Perl scripts
510 (Extended data Fig. 2). All scripts and the data used to process antibody sequences are publicly
511 available on GitHub (<https://github.com/stratust/igpipeline>).

512

513 The frequency distributions of human V genes in anti-SARS-CoV-2 antibodies from this study
514 was compared to 131,284,220 IgH and IgL sequences generated by ⁵⁰ and downloaded from
515 cAb-Rep ⁵¹, a database of human shared BCR clonotypes available at [https://cab-](https://cab-rep.c2b2.columbia.edu/)
516 [rep.c2b2.columbia.edu/](https://cab-rep.c2b2.columbia.edu/). Based on the 97 distinct V genes that make up the 4186 analyzed
517 sequences from Ig repertoire of the 14 participants present in this study, we selected the IgH and
518 IgL sequences from the database that are partially coded by the same V genes and counted them
519 according to the constant region. The frequencies shown in (Fig 2e and Extended Data Fig 3a)
520 are relative to the source and isotype analyzed. We used the two-sided binomial test to check
521 whether the number of sequences belonging to a specific IgHV or IGLV gene in the repertoire is
522 different according to the frequency of the same IgV gene in the database. Adjusted p-values
523 were calculated using the false discovery rate (FDR) correction. Significant differences are
524 denoted with stars.

525
526 Nucleotide somatic hypermutation and CDR3 length were determined using in-house R and Perl
527 scripts. For somatic hypermutations, IGHV and IGLV nucleotide sequences were aligned against
528 their closest germlines using Igbblastn and the number of differences were considered nucleotide
529 mutations. The average mutations for V genes were calculated by dividing the sum of all
530 nucleotide mutations across all participants by the number of sequences used for the analysis. To
531 calculate the GRAVY scores of hydrophobicity⁵² we used Guy H.R. Hydrophobicity scale based
532 on free energy of transfer (kcal/mole)⁵³ implemented by the R package Peptides (the
533 Comprehensive R Archive Network repository; [https://journal.r-project.org/archive/2015/RJ-](https://journal.r-project.org/archive/2015/RJ-2015-001/RJ-2015-001.pdf)
534 [2015-001/RJ-2015-001.pdf](https://journal.r-project.org/archive/2015/RJ-2015-001/RJ-2015-001.pdf)). We used 1409 heavy chain CDR3 amino acid sequences from this
535 study and 22,654,256 IGH CDR3 sequences from the public database of memory B cell receptor

536 sequences⁵⁴. The two-tailed Wilcoxon nonparametric test was used to test whether there is a
537 difference in hydrophobicity distribution.

538

539 **Data availability statement:** Data are provided in SI Tables 1-8. The raw sequencing data and
540 computer scripts associated with Fig. 2 have been deposited at Github
541 (<https://github.com/stratust/igpipeline>). This study also uses data from “A Public Database of
542 Memory and Naive B-Cell Receptor Sequences”⁵⁴, PDB (6VYB and 6NB6) and from “High
543 frequency of shared clonotypes in human B cell receptor repertoires”⁵⁰. Cryo-EM maps
544 associated with data reported in this manuscript will be deposited in the Electron Microscopy
545 Data Bank (EMDB: <https://www.ebi.ac.uk/pdbe/emdb/>).

546

547 **Data presentation**

548 Figures arranged in Adobe Illustrator 2020.

549

550 **Competing interests:** The Rockefeller University has filed a provisional patent application in
551 connection with this work on which Z.W. and M.C.N. are inventors (US patent 63/021,387).

552

553 **Code availability statement:** Computer code to process the antibody sequences is available at
554 GitHub (<https://github.com/stratust/igpipeline>).

555

556 **Acknowledgements:** We thank all study participants who devoted time to our research; Drs.
557 Barry Coller and Sarah Schlesinger, the Rockefeller University Hospital Clinical Research
558 Support Office and nursing staff; Charles M. Rice and all members of the M.C.N. laboratory for

559 helpful discussions and Maša Jankovic for laboratory support; and Dr. Jost Vielmetter and the
560 Protein Expression Center in the Beckman Institute at Caltech for expression assistance. Electron
561 microscopy was performed in the Caltech Beckman Institute Resource Center for Transmission
562 Electron Microscopy and we thank Drs. Songye Chen and Andrey Malyutin for technical
563 assistance. This work was supported by NIH grant P01-AI138398-S1 (M.C.N. and P.J.B.) and
564 2U19AI111825 (M.C.N.); the Caltech Merkin Institute for Translational Research and P50
565 AI150464-13 (P.J.B.), a George Mason University Fast Grant (P.J.B.); R37-AI64003 to P.D.B.;
566 R01AI78788 to T.H.; We thank Dr. Jost Vielmetter and the Protein Expression Center in the
567 Beckman Institute at Caltech for expression assistance C.O.B. is supported by the HHMI Hanna
568 Gray and Burroughs Wellcome PDEP fellowships. C.G. was supported by the Robert S. Wennett
569 Post-Doctoral Fellowship, in part by the National Center for Advancing Translational Sciences
570 (National Institutes of Health Clinical and Translational Science Award program, grant UL1
571 TR001866), and by the Shapiro-Silverberg Fund for the Advancement of Translational Research.
572 P.D.B. and M.C.N. are Howard Hughes Medical Institute Investigators.

574 **Author Contributions:**

575 P.D.B., P.J.B., R.C., T.H., M.C.N, Z.W., F.S., Y.W. F.M. C.O.B, S.F., D.S.B., M.Cipolla.
576 conceived, designed and analyzed the experiments. M.Caskey, C.G., J.A. L, K.W. D.S.B.
577 designed clinical protocols Z.W., F.S., Y.W. F.M. C.O.B, S.F., D.S.B., M.Cipolla, J.D.S. A.G.
578 Z.Y., M.E.A., K.E.H. carried out experiments. C.G., M.Caskey, K.W. D., R.A.C., A.H., K.G.M.
579 recruited participants and executed clinical protocols. I.S., R.P, J.D., J.X. and C.U.O. processed
580 clinical samples. T.Y.O. and V.R. performed bioinformatic analysis. R.C. P.D.B., P.J.B., T.H.,
581 and M.C.N. wrote the manuscript with input from all co-authors.

582 **Extended Data Figures**

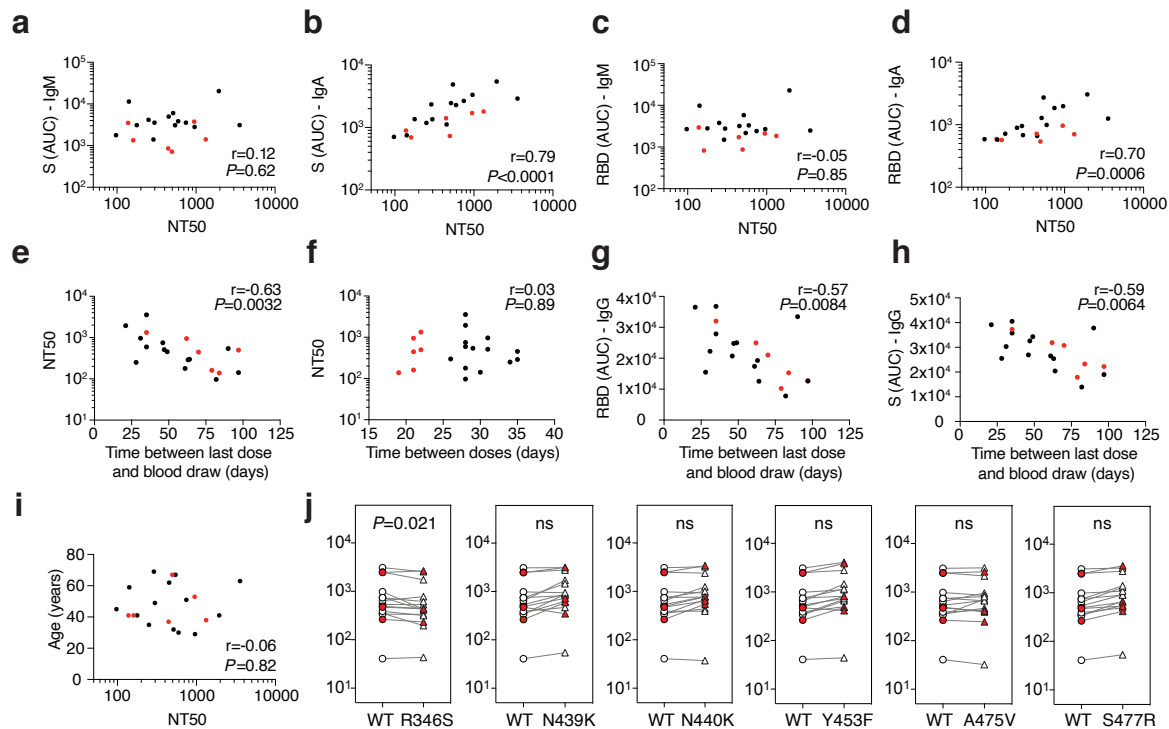

583
 584 **Extended Data Fig. 1. Plasma antibodies against SARS-CoV-2.** **a–f**, Results of ELISAs
 585 measuring plasma reactivity to S (**a,c,e**) and RBD protein (**b,d,f**) of 20 vaccinees (grey curves)
 586 and 8 controls (black curves). **a**, Anti-S IgG. **b**, Anti-RBD IgG. **c**, Anti-S IgM. **d**, Anti-RBD
 587 IgM. **e**, Anti-S IgA. **f**, Anti-RBD IgA. Left, optical density at 450 nm (OD 450 nm) for the
 588 indicated reciprocal plasma dilutions. Right, normalized area under the curve (AUC) values for
 589 the 8 controls and 20 vaccinees. Horizontal bars indicate geometric mean. Statistical significance
 590 was determined using the two-tailed Mann–Whitney U-test. Average of two or more
 591 experiments. **g–i**, Correlations of plasma antibodies measurements. **g**, Normalized AUC for IgG
 592 anti-S plotted against normalized AUC for IgG anti-RBD. **h**, Normalized AUC for IgM anti-S
 593 plotted against normalized AUC for IgM anti-RBD. **i**, Normalized AUC for IgA anti-S plotted
 594 against normalized AUC for IgA anti-RBD. The *r* and *p* values in **g–i** were determined with the

595 two-tailed Spearman's correlation test. Moderna vaccinees are in black and Pfizer-BioNTech in

596 red.

597

598

599 **Extended Data Fig. 2: Plasma neutralizing activity. a**, Anti-S IgM AUC (Y axis) plotted
600 against NT₅₀ (X axis) $r=0.12$, $p<0.6179$. **b**, Anti-S IgA AUC (Y axis) plotted against NT₅₀ (X
601 axis) $r=0.79$, $p<0.0001$. **c**, Anti-RBD IgM AUC (Y axis) plotted against NT₅₀ (X axis) $r=-0.05$
602 $p=0.8502$. **d**, Anti-RBD IgA AUC (Y axis) plotted against NT₅₀ (X axis) $r=0.70$ $p=0.0006$ **e**,
603 NT₅₀ (Y axis) plotted against time between last dose and blood draw (X axis) $r=-0.63$ $p=0.0032$.
604 **f**, NT₅₀ (Y axis) plotted against time between doses (X axis) $r=0.03$ $p=0.8906$. **g**, Anti-RBD IgG
605 AUC (Y axis) plotted against time between last dose and blood draw (X axis) $r=-0.57$ $p=0.0084$.
606 **h**, Anti-S IgG AUC (Y axis) plotted against time between last dose and blood draw (X axis) $r=-$
607 0.59 $p=0.0064$. **i**, Age (Y axis) plotted against NT₅₀ (X axis) $r=-0.06$ $p=0.8150$. The r and p
608 values were determined by two-tailed Spearman's. Moderna vaccinees in black and Pfizer-
609 BioNTech in red. **j**, NT₅₀ values for vaccinee plasma ($n=15$) neutralization of pseudotyped

610 viruses with WT and the indicated RBD-mutant SARS-CoV-2 S proteins; p-values determined
611 using one tailed t-test.
612

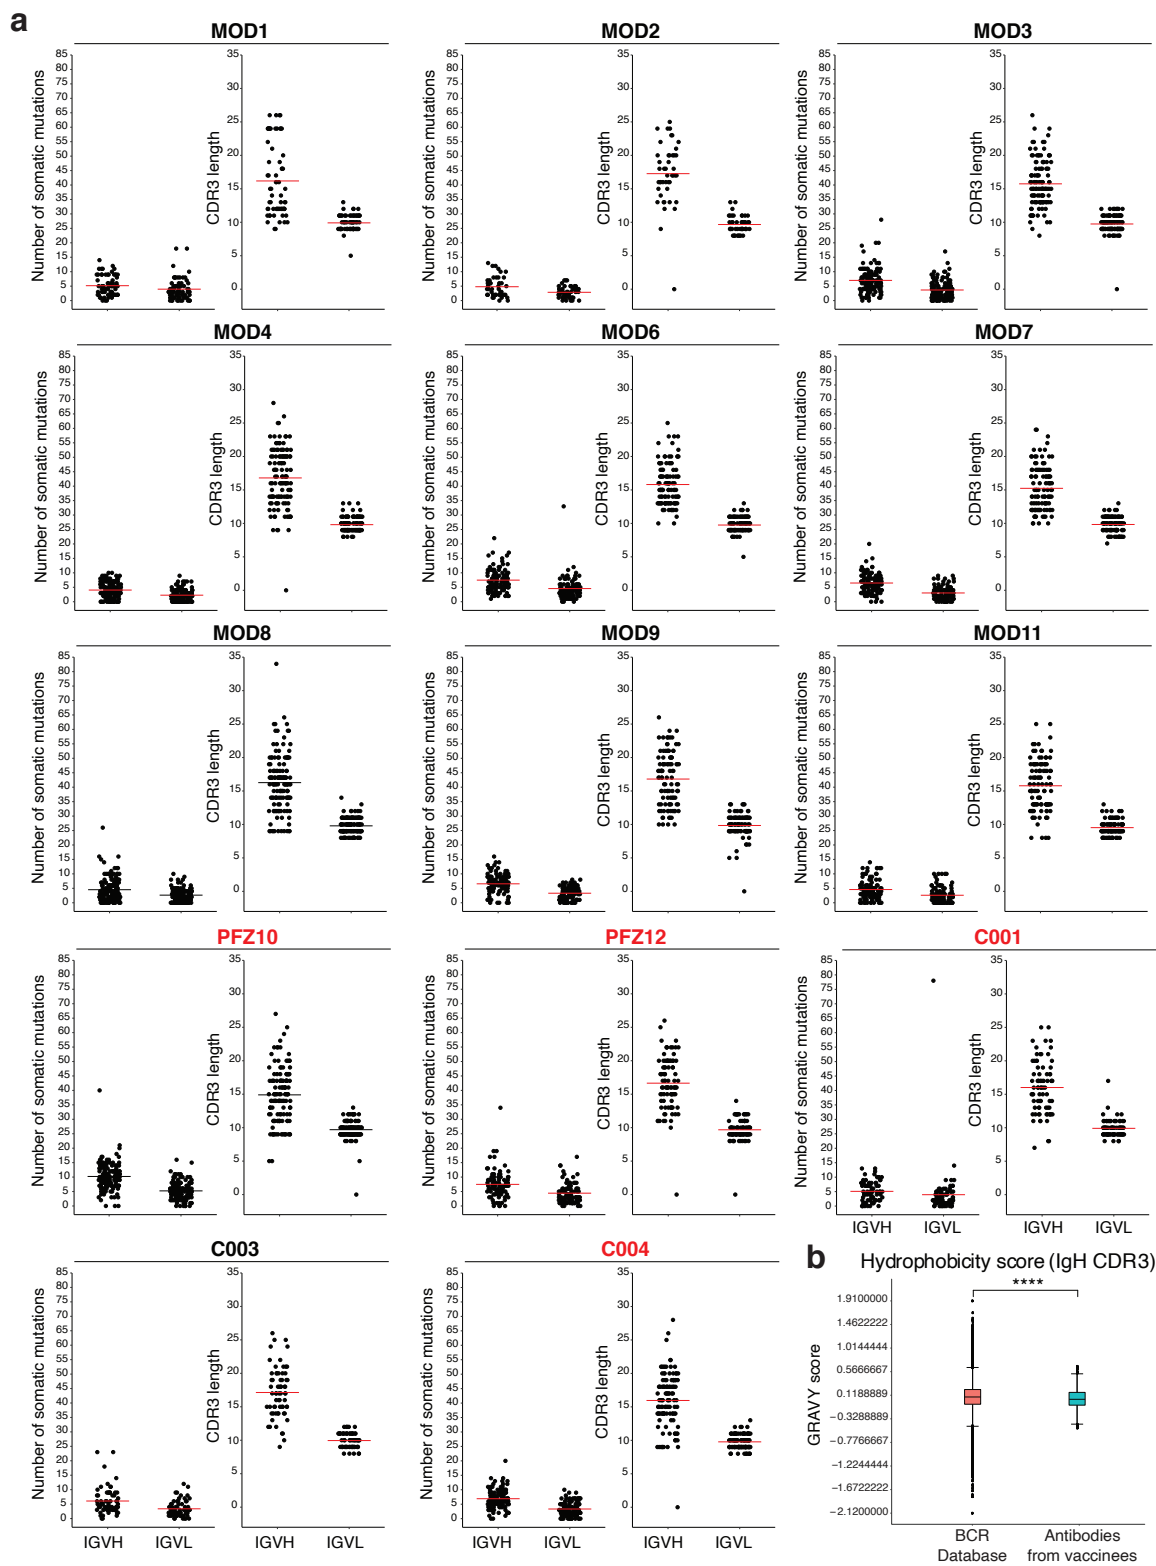

614 **Extended Data Fig. 3: Flow cytometry. a**, Gating strategy used for cell sorting. Gating was on
615 singlets that were CD20+ and CD3-CD8-CD16-OVA-. Sorted cells were RBD-PE+ and RBD-
616 AF647+. **b**, Flow cytometry showing the percentage of RBD-double positive memory B cells
617 from a pre-COVID-19 control (HD) and 15 vaccinees, who received the Moderna vaccine are
618 shown in black and Pfizer-BioNTech vaccine recipients are in red. **c**, the percentage of RBD-
619 binding memory B cells in vaccinees (Y axis) plotted against time between first dose and blood
620 draw (X axis) $r=0.4028$ $p=0.0873$ (left panel), and between last dose and blood draw (X axis)
621 $r=0.3319$ $p=0.1651$ (right panel). Moderna vaccinees in black and Pfizer-BioNTech in red. The r
622 and p values for correlations were determined by two-tailed Spearman's. **d**, Pie charts show the
623 distribution of antibody sequences from 10 individuals in **b**. The number in the inner circle
624 indicates the number of sequences analyzed. Pie slice size is proportional to the number of
625 clonally related sequences. The black outline indicates the frequency of clonally expanded
626 sequences. The r and p values for correlations in **c** were determined by the two-tailed Spearman
627 correlation test.
628

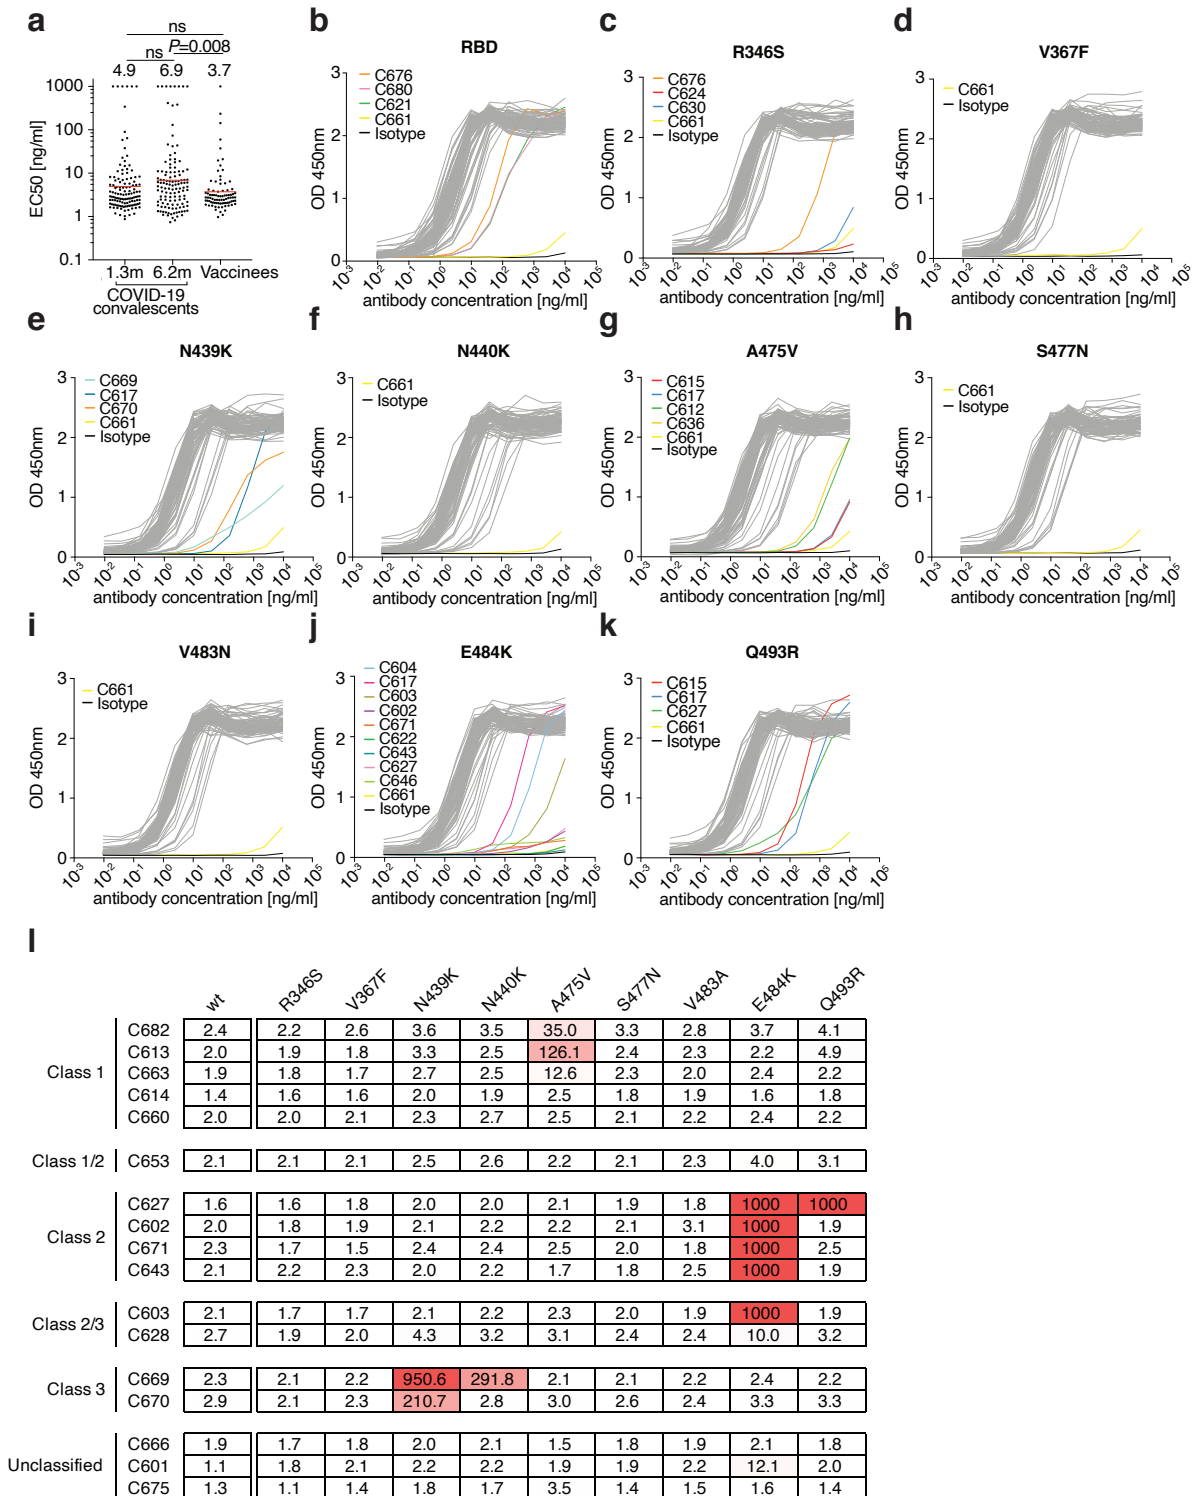

629

630 **Extended Data Fig. 4: Frequency distributions of human VL genes.**

631 Graph shows relative abundance of human IGVK (left) and IgVL (right) genes of Sequence Read
632 Archive accession SRP010970 (orange)⁵⁵, and vaccinees (blue). Two-sided binomial tests with
633 unequal variance were used to compare the frequency distributions., significant differences are
634 denoted with stars. (* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** = $p < 0.0001$). **b.** Sequences
635 from 14 individuals (Extended Data Table 2) with clonal relationships depicted as in **c.**
636 Interconnecting lines indicate the relationship between antibodies that share V and J gene
637 segment sequences at both IGH and IGL. Purple, green and grey lines connect related clones,
638 clones and singles, and singles to each other, respectively.
639

641 **Extended Data Fig. 5: Antibody somatic hypermutation, and CDR3 length. a,** Number of
642 somatic nucleotide mutations in both the IGVH and IGVL in 14 participants (left). Individuals
643 who received the Moderna vaccine are shown in black and Pfizer-BioNTech vaccine recipients
644 in red. For each individual, the number of the amino acid length of the CDR3s at the IGVH and
645 IGVL is shown (right). The horizontal bars indicate the mean. The number of antibody
646 sequences (IGVH and IGVL) evaluated for each participant are n=68 (MOD1), n=45 (MOD2),
647 n=117 (MOD3), n=123 (MOD4), n=110 (MOD6), n=109 (MOD7), n=144 (MOD8), n=102
648 (MOD9), n=132 (PFZ10), n=109 (MOD11), n=91 (PFZ12), n=78 (C001), n=66 (C003), and
649 n=115 (C004). **b,** Distribution of the hydrophobicity GRAVY scores at the IGH CDR3 compared
650 to a public database (see Methods for statistical analysis). The box limits are at the lower and
651 upper quartiles, the center line indicates the median, the whiskers are 1.5× interquartile range and
652 the dots represent outliers. Statistical significance was determined using two-tailed Wilcoxon
653 matched-pairs signed rank test (n.s.=non-significant, **** = $p < 0.0001$).
654

656 **Extended Data Fig. 6: Monoclonal antibody ELISAs. a**, Graph shows antibody binding to
657 SARS-CoV-2 RBD. ELISA EC₅₀ (half-maximal response) values for 84 antibodies isolated from
658 Moderna vaccinees measured at 8 weeks after the boost and from convalescent individuals at 1.3
659 and 6.2 months^{6,7}. Horizontal bars indicate geometric mean. Statistical significance was
660 determined using the two-tailed Mann–Whitney U-test. Average of two or more experiments. **b-**
661 **k**, Graphs show ELISA titrations for antibodies all 84 antibodies against the indicated RBD
662 variants. n = 84 samples and isotype antibody as indicated in the figure. Low-binding antibodies
663 are indicated in colors. Data are representative of two independent experiments. **l**, Table shows a
664 heat map summary of EC₅₀ values for binding to wild type RBD and the indicated mutants for 17
665 top neutralizing antibodies.
666
